

Regular functions and regular maps

$k = \text{Alg. closed field.}$

Recall from last time:

$X \subset \mathbb{A}_k^n$ affine algebraic set.

$f: X \rightarrow k$ regular if it is the restriction of a polynomial function.

$$\begin{aligned} k[X] &= k\text{-algebra of regular functions on } X \\ &\cong k[x_1, \dots, x_n] / I(X). \\ &= \text{Finitely generated nilpotent free } k\text{-algebra.} \end{aligned}$$

Observe - Any finitely generated nilpotent free k -algebra is of the form $k[X]$ for some X .

Why? Let A be such an algebra.

Let $a_1, \dots, a_n \in A$ be a set of generators.

Then we have a map

$$\begin{aligned} \varphi: k[x_1, \dots, x_n] &\rightarrow A \\ x_i &\mapsto a_i. \end{aligned}$$

This map is surjective because $\{a_i\}$ generates A . By the first iso thm

where $I = \text{Ker } \varphi$.

Since A is nilpotent free, I is radical.

Then take $X = V(I)$.

By the Nullstellensatz,

$$k[X] = k[x_1, \dots, x_n] / I(X)$$

$$= k[x_1, \dots, x_n] / I$$

$$\cong A$$

□

As a result we have the dictionary.

Algebra

- Finitely generated reduced k -alg. A

- Max ideal of A

- Given $J \subset A$
 $V(J) = \{m \mid m \supset J\}$

Geometry

- Alg of regular functions on affine alg set X .

- Point of X

- Given $J \subset k[X]$
 $V(J) = \{x \mid f(x) = 0 \forall f \in J\}$

In particular $V(J) = \emptyset$ iff $J = (1)$.

Regular Maps

$X \subset \mathbb{A}^n, Y \subset \mathbb{A}^m$ affine alg sets.
 $f: X \rightarrow Y$ is a regular function if

$\exists f_1, \dots, f_m \in k[X]$ such that

$$f(x) = (f_1(x), \dots, f_m(x)) \quad \forall x \in X.$$

Equivalently, if there exist F_1, \dots, F_m in $k[x_1, \dots, x_n]$ such that
 $f(x) = (F_1(x), \dots, F_m(x)) \quad \forall x \in X.$

Ex 1: $f: X \rightarrow \mathbb{A}^1$ regular map
 $\Leftrightarrow f$ is a regular function.

Ex 2: $L: \mathbb{A}^n \rightarrow \mathbb{A}^m$ linear transfⁿ
 is regular.

Ex 3: Projections $\mathbb{A}^n \rightarrow \mathbb{A}^1$

Ex 4: Compositions of regular maps
 are regular

Ex 5: $X \subset \mathbb{A}^n$ Zariski closed.

The inclusion $X \rightarrow \mathbb{A}^n$ is regular.

Def: A regular $f: X \rightarrow Y$ is an isomorphism if there exists a regular inverse map $g: Y \rightarrow X$.

Ex 6: $X = \mathbb{A}^1$
 $Y = \{y^2 - x^3 = 0\} \subset \mathbb{A}^2$

$f: X \rightarrow Y$

$t \mapsto (t^2, t^3)$ is a regular

bijection but not an isomorphism!

How does one see that it's not an iso? Wait and see....

Let $\varphi: X \rightarrow Y$ be any map.

Then we get an induced map

$\varphi^*: \text{Functions on } Y \rightarrow \text{Functions on } X$
 $f \mapsto f \circ \varphi$.

Proposition: φ is regular if and only if φ^* sends regular functions on Y to regular functions on X .

Pf: Suppose φ is regular.

If $f: Y \rightarrow A^1$ is a regular function then φ^*f is regular because composition of regular maps is regular.

Conversely, suppose $\varphi^*(f)$ is regular for every regular f . Let $\varphi(x) = (\varphi_1(x), \dots, \varphi_m(x))$. We want to show each $\varphi_i(x)$ is regular. But $\varphi_i = \varphi^*(x_i)$ and $x_i \in k[X]$ is regular. \square

Thus a regular map $\varphi: Y \rightarrow X$ induces a k -alg. hom $\varphi^*: k[Y] \rightarrow k[X]$.

Prop: Let $\alpha: k[Y] \rightarrow k[X]$ be a k -alg. hom. Then there is a unique regular $\varphi: X \rightarrow Y$ such that $\alpha = \varphi^*$.

Pf: Suppose $Y = V(J) \subset A^m$

Then $k[Y] = k[y_1, \dots, y_m] / J$

$$k[X] = k[x_1, \dots, x_n] / I.$$

Let $\varphi_i = \alpha(y_i) \in k[X]$

Consider $\varphi := (\varphi_1, \dots, \varphi_m) : X \rightarrow \mathbb{A}^m$.

Let us check that φ maps X to Y .

To see this, we must show that

$$f(\varphi_1(x), \dots, \varphi_m(x)) = 0 \quad \forall x \in X$$

$$f \in J.$$

But $f(\varphi_1(x), \dots, \varphi_m(x))$

$$= f(\alpha(y_1), \dots, \alpha(y_m))$$

$$= \alpha(f(y_1, \dots, y_m))$$

$$= \alpha(0) = 0.$$

So $\varphi : X \rightarrow Y$. Note $\varphi^*(y_i) = \alpha(y_i)$

so $\varphi^* = \alpha$ because $\{y_i\}$ generate $k[Y]$.

Finally, if $\varphi : X \rightarrow Y$ is such that

$\varphi^* = \alpha$, and $\varphi = (\varphi_1, \dots, \varphi_m)$, then

$\varphi^*(y_i) = \varphi_i = \alpha(y_i)$, so there is only one possible φ .

□.

Conseq: $X \rightsquigarrow k[X]$ defines an equivalence of categories

$$\left\{ \begin{array}{l} \text{Affine alg} \\ \text{sets with} \\ \text{regular maps} \end{array} \right\} \longrightarrow \left\{ \begin{array}{l} \text{Fin gen reduced} \\ k\text{-algebras} \\ \text{with } k\text{-alg.} \\ \text{homs} \end{array} \right\}$$

Ex: $X = \mathbb{A}^1$
 $Y = V(y^2 - x^3) \subset \mathbb{A}^2$

$$k[X] = k[t] \quad k[Y] = k[x, y] / (y^2 - x^3)$$

$$\varphi: X \rightarrow Y \quad \varphi(t) = (t^2, t^3)$$

$$\begin{aligned} \varphi^*: k[Y] &\rightarrow k[X] \\ x &\mapsto t^2 \\ y &\mapsto t^3. \end{aligned}$$

φ^* is not an isomorphism!
 Any element in the image of φ^* has vanishing linear term.

Next: Algebraic varieties (more general spaces than affine algebraic sets).

To do that, we want to define the notion of regularity more locally.

Let $X \subset \mathbb{A}^n$ be an affine alg. set, $f: X \rightarrow k$ a function, and $x \in X$ a point. We say that f is regular at x if there exist $F, G \in k[x_1, \dots, x_n]$ with $G(x) \neq 0$ such that $f = F/G$ on the open set $X \cap \{G \neq 0\}$.

Claim: If f is regular at all $x \in X$, then f is regular (i.e. given by a polynomial).

Pf: $\forall x \in X \quad \exists F_x \text{ \& } G_x \text{ s.t.}$
 $G_x(x) \neq 0 \text{ \& } f = F_x/G_x.$

Then $\{G_x\}$ has no common zero on $X \Rightarrow \langle G_x \rangle = (1)$ in $k[X]$.

Write $1 = h_1 G_1 + \dots + h_e G_e$

Then X is the union of the opens

$$f = \frac{F_i}{G_i}$$

Take $F = h_1 F_1 + \dots + h_e F_e \in k[X]$

Then $F = f$ on X .

□

The above motivates the following.

Let $X \subset \mathbb{A}^n$ be an affine alg. set and $U \subset X$ an open set. A function $f: U \rightarrow k$ is regular on U if it is regular at every $x \in U$. That is for every $x \in U$ $\exists F, G \in k[x_1, \dots, x_n]$ $G(x) \neq 0$ such that

$$f = \frac{F}{G} \text{ on } U \cap \{G \neq 0\}.$$

Similarly $\phi: U \rightarrow Y$ is regular if $\phi = (\phi_1, \dots, \phi_m)$ where each ϕ_i is a regular function on U .

Now we have

$$\left\{ \begin{array}{c} \text{affine algebraic} \\ \text{varieties} \end{array} \right\} = \left\{ \begin{array}{c} \text{affine alg. subsets} \\ \text{of } \mathbb{A}^n_k \end{array} \right\}$$

$$\left\{ \begin{array}{c} \text{Quasi-affine} \\ \text{varieties} \end{array} \right\} = \left\{ \begin{array}{c} \text{open subsets of} \\ \text{affine alg subsets} \\ \text{of } \mathbb{A}^n_k \end{array} \right\}$$

Morphisms = Regular maps

Examples: ①

$$\text{Let } X = \mathbb{A}^1 \setminus \{0\}.$$

$$Y = V(xy - 1) \subset \mathbb{A}^2.$$

Then we have an isomorphism
 $X \xrightarrow{\sim} Y.$

In particular X is (isomorphic to) an affine algebraic variety!

The iso is given by $X \rightarrow Y$

and the inverse is

$$\begin{aligned} Y &\rightarrow X \\ (x, y) &\mapsto x. \end{aligned}$$

② More generally, let
 $f \in k[x_1, \dots, x_n]$ and
 $X = \{x \in \mathbb{A}^n \mid f(x) \neq 0\}$
 $= \mathbb{A}^n - V(f).$

$$\begin{aligned} \text{Let } Y \subset \mathbb{A}^{n+1} &= \{(x_1, \dots, x_n, y)\} \\ Y &= V(y f(x_1, \dots, x_n) - 1). \end{aligned}$$

Then we have an iso $X \xrightarrow{\sim} Y$
 given by

$$(x_1, \dots, x_n) \mapsto (x_1, \dots, x_n, \frac{1}{f(x_1, \dots, x_n)})$$

with inverse $(x_1, \dots, x_n, y) \mapsto (x_1, \dots, x_n).$

In particular X is an affine alg.
 variety!

③ Not all quasi-affine varieties are isomorphic to affine varieties.

To see an example, recall that affine alg. varieties satisfy the Nullstellensatz — there is a bijection between max ideals of $k[X]$ and points of X given by $m \mapsto V(m)$.

Take $X = \mathbb{A}^2 \setminus \{(0,0)\} \subset \mathbb{A}^2$

Claim: The k -algebra of regular functions on X is the same as $k[\mathbb{A}^2] = k[x, y]$.

Pf: Deferred.

But now $m = (x, y) \subset k[X]$ is a non-unit ideal such that $V(m) = \emptyset$ (in X). Therefore, X cannot be affine.

[illegible]
